

Chemistry Ch 5.2: Chemical Bonds

Chapter 5, Chemical Bonding · kitab ke page 73 se 94

Chemical bond kya hai

Wo **kheench (force of attraction)** jo do atoms ko aapas mein **jore** rakhti hai.

Bond banta tab hai jab atoms mil kar **pehle se kam energy** wali halat mein pohanch jayein. Kam energy ka matlab hai **zyada mustahkam**.

Do lafz jo faisla karte hain

Electropositive: wo element jo electron **asaani se de** deta hai. Ye **dhatein** hain, aur periodic table ke **bayein** taraf hain.

Electronegative: wo element jo electron **apni taraf kheenchta** hai. Ye **ghair dhatein** hain, aur **dayein** taraf hain.

Isi se bond ki qism tay hoti hai

Kaun kis se mil raha hai	Kaunsa bond
Dhat + ghair dhat (electropositive + electronegative)	Ionic: ek deta hai, doosra leta hai
Ghair dhat + ghair dhat (dono electronegative)	Covalent: dono share karte hain
Dhat + dhat (dono electropositive)	Metallic: electron ka samundar

Yani sawal mein do element diye jayein to pehle dekhein ke wo table mein **kahan** hain. Us se bond ki qism khud bakhud nikal aati hai.

Quiz

1. Define a **chemical bond**, and explain in terms of energy why atoms form one.
2. Explain the difference between an **electropositive** and an **electronegative** element, say where each sits in the periodic table, and give the type of bond formed by metal plus non-metal, non-metal plus non-metal, and metal plus metal.
